Key findings - Climate change, impacts and vulnerability in Europe 2016

Download key findings as a pdf brochure

Key observed and projected climate change and impacts for the main biogeographical regions in Europe:

Arctic region Temperature rise much larger than global average Decrease in Arctic sea ice coverage Decrease in Greenland ice sheet Decrease in permafrost areas Increasing risk of biodiversity loss Some new opportunities for the exploitation of natural resources and for sea transportation

Risks to the livelihoods of indigenous peoples Coastal zones and regional seas Sea level rise Increase in sea surface temperatures Increase in ocean acidity Northward migration of marine species Risks and some opportunities for fisheries

Changes in phytoplankton communities

Increasing number of marine dead zones

Increasing risk of water-borne diseases

Increasing damage risk from winter storms

Mediterranean region Large increase in heat extremes Decrease in precipitation and river flow Increasing risk of droughts Increasing risk of biodiversity loss Increasing risk of forest fires Increased competition between different water users Increasing water demand for agriculture Decrease in crop yields Increasing risks for livestock production Increase in mortality from heat waves Expansion of habitats for southern disease vectors Decreasing potential for energy production Increase in energy demand for cooling

Decrease in summer tourism and potential increase in other seasons

Most economic sectors negatively affected High vulnerability to spillover effects of climate change from outside Europe

Increase in multiple climatic hazards

Atlantic region Increase in heavy precipitation events

Increase in river flow Increasing risk of river and coastal flooding Increasing damage risk from winter storms Decrease in energy demand for heating Increase in multiple climatic hazards

Boreal region Increase in heavy precipitation events Decrease in snow, lake and river ice cover Increase in precipitation and river flows Increasing potential for forest growth and increasing risk of forest pests

Increase in crop yields Decrease in energy demand for heating Increase in hydropower potential Increase in summer tourism

Mountain regions

Temperature rise larger than European

Decrease in glacier extent and volume Upward shift of plant and animal species High risk of species extinctions Increasing risk of forest pests Increasing risk from rock falls and landslides

Changes in hydropower potential Decrease in ski tourism

Continental region Increase in heat extremes Decrease in summer precipitation Increasing risk of river floods Increasing risk of forest fires Decrease in economic value of forests Increase in energy demand for cooling

Humans have significantly changed the climate and increased the magnitude of many extreme weather events

- Climate change is continuing globally and in Europe. Land and sea temperatures are increasing; precipitation patterns are changing, generally making wet regions in Europe wetter, particularly in winter, and dry regions drier, particularly in summer; sea ice extent, glacier volume and snow cover are decreasing; sea levels are rising; and climate-related extremes such as heat waves, heavy precipitation and droughts are increasing in frequency and intensity in many regions.
- New record levels of some climatic variables have been established in recent years, notably global and European temperature in 2014 and again in 2015, global sea level in 2015 and winter Arctic sea ice extent in 2016. Some climatic changes have accelerated in recent decades, such as global sea level rise and the decline of the polar ice sheets.
- Global climate change has substantially increased the probability of various recent extreme weather and climate events in Europe. The reliability of this finding has been strengthened by recent progress in extreme weather attribution techniques.
- Climate change will continue for many decades to come. Improved climate projections provide further evidence that future climate change will increase climate-related extremes (e.g. heat waves, heavy precipitation, droughts, top wind speeds and storm surges) in many European regions.

Climate change has wide-ranging impacts on ecosystems, economic sectors and human health

- The observed changes in climate are already having wide-ranging impacts on ecosystems, economic sectors and human health and well-being in Europe. Recent studies show that various observed changes in the environment and society, such as changes in forest species, the establishment of invasive alien species and disease outbreaks, have been caused or enhanced by global climate change.
- Ecosystems and protected areas are under pressure from climate change and other stressors, such as land use change. The observed impacts of climate change are a threat to biodiversity in Europe, but they also affect forestry, fishery, agriculture and human health. In response to climate change, many land-based animal and plant species are changing their life cycles and are migrating northwards and to higher altitudes; regional extinctions have been observed; various invasive alien species have established themselves or have expanded their range; and various marine species, including commercially important fish stocks, are migrating northwards.

Different regions and sectors in Europe are affected differently by climate change

- Most impacts of climate change across Europe have been adverse, although some impacts have been beneficial. The rise in sea level has increased flood risks and contributed to erosion along European coasts. The observed increase in heat waves has had significant effects on human health, in particular in cities. Heat waves are also increasing the risk of electricity blackouts and forest fires. Transport and tourism have also been affected by climate change, with large regional differences. Examples of beneficial impacts of climate change include a decrease in heating demand and some benefits to agriculture in northern Europe.
- Climate change is affecting all regions in Europe, but the impacts are not uniform. South-eastern and southern Europe are projected to be hotspot regions, having the highest numbers of severely affected sectors and domains. Coastal areas and floodplains in the western parts of Europe are also multi-sectoral hotspots. The Alps and the Iberian Peninsula are additional hotspots for ecosystems and their services. Ecosystems and human activities in the Arctic will be strongly affected owing to the particularly fast increase in air and sea temperatures and the associated melting of land and sea ice.
- Economic costs can potentially be high, even for modest levels of climate change, and these costs rise significantly for scenarios of greater levels of warming. The projected damage costs from climate change are highest in southern Europe. However, estimates of the projected economic impacts of climate change in Europe consider only some sectors and show considerable uncertainty.

Climate change impacts interact with other developments inside and outside Europe

- Future climate change will interact with other socio-economic developments, including the ageing of the population and increasing urbanisation across Europe, projected decreases in population size in eastern Europe, and a narrowing economic gap between eastern and western parts of Europe. The water sector, agriculture, forestry and biodiversity show strong interdependencies, and are also related to changing land-use patterns and population change.
- Europe is vulnerable to climate change impacts outside Europe through six major pathways: the trade of agricultural commodities, the trade of non-agricultural commodities, infrastructure and transport, geopolitics and security risks, human mobility related to migration and finance. The strongest evidence for Europe's vulnerability to cross--border impacts are the economic effects seen as a result of climate-related global price volatilities and disruptions to transportation networks. The Mediterranean area is most vulnerable to shocks in the flow of agricultural commodities, while small, open and highly developed European economies are particularly vulnerable to shocks in the flow of non-agricultural commodities. European vulnerability to cross-border effects is expected to increase in the coming decades, but quantitative projections are not available.

Mitigation of climate change is required to limit the longterm risks from climate change

■ The magnitude of future climate change and its impacts from the middle of the century onwards depend on the effectiveness of global climate mitigation efforts. The magnitude of climate change and its impacts can be substantially reduced by an ambitious global mitigation policy compatible with the mitigation goal of the 2015 Paris Agreement under the United Nations Framework Convention on Climate Change (UNFCCC) of keeping the increase in global average temperature to well below 2 °C above pre-industrial levels.

Adaptation to climate change is necessary to reduce short- and long-term risks from climate change

■ Climate change adaptation strategies, policies and actions, including the mainstreaming of them into other policies, are progressing at all governance levels (European Union (EU), transnational, national and local levels). Further actions could include enhancing policy coherence across EU environmental and sectoral policies; effective and efficient action across all levels of governance, through multi-level governance and transnational cooperation platforms; enhancing flexible 'adaptive management' approaches; combining technological solutions, ecosystem-based approaches and 'soft' measures; involving the private sector; and more emphasis on 'transformational' adaptation actions as a complement to 'incremental' adaptation.

Better monitoring, research and information exchange can improve the knowledge base for adaptation

- The knowledge base regarding climate change impacts, vulnerability, risk and adaptation assessments in Europe could be enhanced, e.g. through improved monitoring and reporting of climate-related extremes and the associated damage, enhanced national and sectoral assessments and their reporting, and further monitoring, reporting and evaluation of adaptation actions at the national level. More knowledge would also be useful on the costs and benefits of adaptation options and on interdependencies, synergies and trade-offs between adaptation policies and other policies and actions. EU-funded and national research can address adaptation knowledge gaps and stimulate innovation.
- The use of European, transnational and national climate change and adaptation services by stakeholders could be further improved. The European Commission's 'adaptation preparedness scoreboard', which assesses the progress of Member States using process-based indicators could be complemented by quantitative information. The indicators of the Sendai Framework for Disaster Risk Reduction for weather- and climate-related hazards are expected to be relevant for climate change adaptation.

About the report

'Climate change, impacts and vulnerability in Europe 2016' presents a primarily indicator-based assessment of past and projected climate change and its impacts in Europe, consisting of six main parts:

- (1) Policy context;
- (2) Changes in the climate system;
- (3) Climate change impacts on environmental systems;
- (4) Climate change impacts on society;
- (5) Multi-sectoral vulnerability and risks; and
- (6) Strengthening the knowledge base.

The report has been developed by the European Environment Agency in collaboration with the Joint Research Centre, European Centre for Disease Prevention and Control, World Health Organisation Regional Office for Europe and three European Topic Centres (ETC-CCA, ETC-BD, ETC-ICM). The work has been guided by an external advisory group and the content of the report has been reviewed by independent experts.
